

# MFI: Multi-range Feature Interchange for Video Action Recognition

Sikai Bai, Qi Wang and Xuelong Li Center for OPTical IMagery Analysis and Learning (OPTIMAL), Northwestern Polytechnical University

## Introduction

### **Motivation**:

 $\succ$  Video action recognition is a fundamental yet challenging task in the field of computer vision.

T Frames

Short-range features motion and long-range dependencies are two complementary and vital cues for action recognition in videos.

 $\succ$  It is still unclear how to capture temporal information with complex evolution on multiple ranges using an efficient and effective way.

> Feature interchange: the features from the colored regions bi-directionally shift in the feature map of video models.

### **Contribution:**

- Perform channel-wise temporal interchange (CTI) along the temporal dimension to effectively encode shortrange motion features.
- ➢ Construct graph-based regional interchange (GRI) module to learn efficiently long-range dependencies using graph convolution.
- > Propose a novel multi-range feature interchange (MFI) network to integrate the proposed two modules.

### Fig. 2: The overview architecture of Multi-range Feature Interchange Network for video action recognition.

Following [1], T sampled frames are obtained from a video as the input of the network. 2D ResNet-50 is utilized as the backbone, and all original bottleneck blocks are replaced by the proposed STI blocks. We also insert two GRI modules between middle and top STI blocks. The global temporal pooling is applied to average action predictions for all of the sampled frames.

## **Architecture Details**

- Channel-wise Temporal Interchange (CTI) Module
  - The temporal difference can be obtained by calculating the difference between the features of two consecutive frames.

 $H_{c}^{T} = Conv_{trans} \otimes Y_{c}^{t+1} - Y_{c}^{t}, \quad t \in [1, T-1].$ 

Temporal interchange operation. •

> $H_{ic}^{t}[h, w, c] = H^{t+1}[h, w, c], \quad t \in [1, T-1], c \in [0, C/8r],$  $H_{ic}^{t}[h, w, c] = H^{t-1}[h, w, c], \quad t \in [2, T], c \in [C/8r, C/4r],$

 $H_{ic}^{t}[h, w, c] = H^{t}[h, w, c], \quad t \in [1, T], c \in [C/4r, C/r].$ 

- Channel-wise Temporal Interchange (CTI) Module
  - Transform from the features in a regular feature map to the state of nodes in a nongrid graph.

 $W_t = [Conv_{trans} \otimes \Phi_r(X)]^T, \quad W_t \in \mathbb{R}^{N \times L},$  $V_t = W_t * \Phi_r(X), \qquad V_t \in \mathbb{R}^{N \times C}.$ 

Graph Convolutional Operation. The nodes propagate their state with each other.  $\bullet$ 

 $V_{out} = Re LU(F(V_t, A_g, W_g) + V_t)$ 

Achieves competitive results by using very limited computing cost.
