

Int. Conf. on Pattern Recognition (ICPR) 2020

On learning Random Forests for Random Forest-clustering

Manuele Bicego, Francisco Escolano

University of Verona (Italy), Universidad de Alicante (Spain)

manuele.bicego@univr.it, sco@dccia.ua.es

Random Forest Clustering

- ♦ Random Forests: powerful and interpretable tools based on aggregation of decision trees
- ♦ Main exploitation: classification and regression

In other scenarios, such as **clustering**, they have been less investigated

Random Forest Clustering

- ♦ Main RF-clustering approaches:
 - ♦ Methods based on direct exploitation of RF (or RF-like schemes) to get clustering
 - ♦ Methods which exploit description capabilities of RF to derive a dissimilarity measure (to be used with standard distance-based clustering methods)

Random Forest Clustering

- ♦ Main RF-clustering approaches:
 - ♦ Methods based on direct exploitation of RF (or RF-like schemes) to get clustering
 - ♦ Methods which exploit description capabilities of RF to derive a dissimilarity measure (to be used with standard distance-based clustering methods)

The general scheme

Objects to be clustered

$$\mathbf{X} = \begin{bmatrix} x_{11} & \cdots & x_{1N} \\ \vdots & \ddots & \vdots \\ x_{d1} & \cdots & x_{dN} \end{bmatrix}$$

The general scheme

Objects to be clustered

$$\mathbf{X} = \begin{bmatrix} x_{11} & \cdots & x_{1N} \\ \vdots & \ddots & \vdots \\ x_{d1} & \cdots & x_{dN} \end{bmatrix}$$

Random Forest

STEP 1: Build a Random Forest on **X**

The general scheme

Objects to be clustered

$$\mathbf{X} = \begin{bmatrix} x_{11} & \cdots & x_{1N} \\ \vdots & \ddots & \vdots \\ x_{d1} & \cdots & x_{dN} \end{bmatrix}$$

Random Forest

STEP 1: Build a Random Forest on **X**

Problem: no labels!

Classic approach:

Generate negative class +
classification Random Forest

The general scheme

Objects to be clustered

$$\mathbf{X} = \begin{bmatrix} x_{11} & \cdots & x_{1N} \\ \vdots & \ddots & \vdots \\ x_{d1} & \cdots & x_{dN} \end{bmatrix}$$

Random Forest

Dissimilarity Matrix

STEP 2: Extract a dissimilarity
between points **through** the RF

$$D = [dis(\mathbf{x}_i, \mathbf{x}_j)]$$

The general scheme

Objects to be clustered

$$\mathbf{X} = \begin{bmatrix} x_{11} & \cdots & x_{1N} \\ \vdots & \ddots & \vdots \\ x_{d1} & \cdots & x_{dN} \end{bmatrix}$$

Random Forest

STEP 2: Extract a dissimilarity between points **through** the RF

Dissimilarity Matrix

Example: two points are similar if, in the different RF trees, they fall **very often** in the same leave (similar answers to tests)

$$D = [dis(\mathbf{x}_i, \mathbf{x}_j)]$$

The general scheme

Objects to be clustered

$$\mathbf{X} = \begin{bmatrix} x_{11} & \cdots & x_{1N} \\ \vdots & \ddots & \vdots \\ x_{d1} & \cdots & x_{dN} \end{bmatrix}$$

Random Forest

Dissimilarity Matrix

$$D = [dis(\mathbf{x}_i, \mathbf{x}_j)]$$

Distance-based
clustering method

STEP 3: Clustering via any
distance-based clustering
method

Example:
Spectral
Clustering

The general scheme

Objects to be clustered

$$\mathbf{X} = \begin{bmatrix} x_{11} & \cdots & x_{1N} \\ \vdots & \ddots & \vdots \\ x_{d1} & \cdots & x_{dN} \end{bmatrix}$$

Random Forest

Dissimilarity Matrix

$$D = [dis(\mathbf{x}_i, \mathbf{x}_j)]$$

Distance-based
clustering method

Partition

$$\begin{matrix} \mathcal{C}^1 \\ \mathcal{C}^2 \\ \vdots \\ \mathcal{C}^K \end{matrix}$$

Our Focus

Objects to be clustered

$$\mathbf{X} = \begin{bmatrix} x_{11} & \cdots & x_{1N} \\ \vdots & \ddots & \vdots \\ x_{d1} & \cdots & x_{dN} \end{bmatrix}$$

Random Forest

Dissimilarity Matrix

$$D = [dis(\mathbf{x}_i, \mathbf{x}_j)]$$

Distance-based
clustering method

Partition

$$\begin{matrix} \mathcal{C}^1 \\ \mathcal{C}^2 \\ \vdots \\ \mathcal{C}^K \end{matrix}$$

Learning Random Forests

- ♦ **STEP1** (Learning of RF) has received poor attention by researchers (main efforts are on **STEP 2**)
 - ♦ Most of the cases: generation of a synthetic negative class plus training of a standard classification RF
 - ♦ Few others: use of completely randomized RF (as in Extremely Randomized Trees [Geurts et al, ML06])
- ♦ Our position: **this step is crucial!**

Learning Random Forests

- ♦ **Our contributions:**
 - ♦ We propose two novel solutions for learning RF in RF-clustering
 - ♦ We perform a thorough experimental evaluation to show that a proper learning of RF is fundamental in RF clustering
 - ♦ We derive a set of guidelines to suggest the proper learning depending on the given dataset

Contribution 1: novel learning schemes

- ♦ **Gaussian Density Random Forests**

- ♦ Random Forests designed for density estimation (Criminisi et al 2012) but never used for RF-clustering
- ♦ Trees are built so that in each node the **Gaussian entropy** is maximized
 - ♦ Assumption: data in each node follow a Gaussian distribution

Contribution 1: novel learning schemes

- ♦ **Rényi Random Forests**

- ♦ Novel Random Forests we introduce in this paper
- ♦ Trees are built so that in each node the **Rényi entropy** is maximized
 - ♦ The Rényi entropy is estimated using **non parametric** bypass entropy estimator
 - ♦ Appropriate when the Gaussianity assumption is too strict

All details are in the paper!

Contribution 2: thorough experimental evaluation

- We employed 8 standard UCI-ML datasets
- We analyse different options for all the steps
 - **STEP 1:** 4 learning strategies (ClassRF, RandRF, GaussRF and RenyiRF), with different parametrizations
 - **STEP 2:** 4 different distances
 - Shi: [Shi et al 2006]
 - Zhu2, Zhu3: [Zhu et al, CVPR14]
 - Ting: [Ting et al, KDD16]
 - **STEP 3:** 3 different distance-based methods
 - Spectral clustering, Affinity Propagation, Hierarchical clustering (Ward-Link)

Results

- ♦ All the numbers are in the paper!
- ♦ Main findings:
 - ♦ The classic learning scheme is hardly the best solution (in less than 2% of the cases)
 - ♦ Random Forests based on data entropy (Gaussian or Rényi) seem to be very promising
 - ♦ Also random training works adequately well, especially for high dimensional datasets

Contribution 3: guidelines for RF-clustering

- ♦ We provide suggestions for **all STEPS** of RF-clustering (details in the paper)
- ♦ For the learning:
 - ♦ If the problem is highly dimensional → use the Random-RF scheme;
 - ♦ If the problem is low dimensional:
 - ♦ Train with Gauss-RF strategy
 - ♦ Check the Gaussianity of the resulting clusters (e.g. with Royston's test);
 - ♦ If all clusters are non-Gaussian, discard the trained RF and train a RF with the Rényi-RF strategy

Conclusions

- ♦ The proper learning of Random Forests for RF-clustering is crucial
- ♦ Methods based on data entropy are adequate for low dimensional datasets
- ♦ Methods based on random mechanisms can work very well, especially in high dimensional spaces

Objects to be clustered

$$\mathbf{X} = \begin{bmatrix} x_{11} & \cdots & x_{1N} \\ \vdots & \ddots & \vdots \\ x_{d1} & \cdots & x_{dN} \end{bmatrix}$$

Random Forest

Thanks for your attention!
